## Hybridization.

The concept of hybridization was introduced by Pauling and Slater. It is defined as the intermixing of dissimilar orbitals of the same atom but having slightly different energies to form same number of new orbitals of equal energies and identical shapes. The new orbitals so formed are known as hybrid orbitals.

## Characteristics of hybridization

(1) Only orbitals of almost similar energies and belonging to the same atom or ion undergoes hybridization.
(2) Hybridization takes place only in orbitals, electrons are not involved in it.
(3) The number of hybrid orbitals produced is equal to the number of pure orbitals, mixed during hybridization.
(4) In the excited state, the number of unpaired electrons must correspond to the oxidation state of the central atom in the molecule.
(5) Both half filled orbitals or fully filled orbitals of equivalent energy can involve in hybridization.
(6) Hybrid orbitals form only sigma bonds.
(7) Orbitals involved in $\pi$ bond formation do not participate in hybridization.
(8) Hybridization never takes place in an isolated atom but it occurs only at the time of bond formation.
(9) The hybrid orbitals are distributed in space as apart as possible resulting in a definite geometry of molecule.
(10) Hybridized orbitals provide efficient overlapping than overlapping by pure $s, p$ and $d-$ orbitals.
(11) Hybridized orbitals possess lower energy.

Depending upon the type and number of orbitals involved in intermixing, the hybridization can be of various types namely sp, sp2, sp3, sp3d, dsp2, sp3d2, sp3d3. The nature and number of orbitals involved in the above mentioned types of hybridization and their acquired shapes are discussed in following table

| Type of <br> hy- | Character | Geometry of <br> molecules as per | No. <br> of | No. of <br> lone | Actual <br> shape of | Example |

Short trick to find out hybridization : The structure of any molecule can be predicted on the basis of hybridization which in turn can be known by the following general formulation.
$H=\frac{1}{2}(V+M-C+A)$
Where $H=$ Number of orbitals involved in hybridization viz. 2, 3, 4, 5, 6 and 7, hence nature of hybridization will be $\mathrm{sp}, \mathrm{sp2}$, sp3, sp3d, sp3d2, sp3d3 respectively.
$\mathrm{V}=$ Number electrons in valence shell of the central atom, $\quad \mathrm{M}=$ Number of monovalent atom
$C=$ Charge on cation,
$A=$ Charge on anion

Few examples are given below to illustrate this:

Type : (A) When the central atom is surrounded by monovalent atoms only, e.g. $\mathrm{BeF} 2, \mathrm{BCl} 3, \mathrm{CCl4}$, $\mathrm{NCl} 3, \mathrm{PCl} 5, \mathrm{NH} 3, \mathrm{H} 2 \mathrm{O}, \mathrm{OF} 2, \mathrm{TeCl4}, \mathrm{SCl2}$, IF7, CIF3, SF4, SF6, XeF2, XeF4, etc. Let us take the case of PCl 5 . ${ }^{H=\frac{1}{2}(5+5-0+0)=5}$. Thus, the type of hybridization is sp3d.

Type : (B) When the central atom is surrounded by divalent atoms only; e.g. CO2, CS2, SO2, SO3,
XeO 3 etc. Let us take the case of SO . $H=\frac{1}{2}(6+0-0+0)=3$. Thus, the type of hybridization in SO3 is sp2.

Type : (C) When the central atom is surrounded by monovalent as well as divalent atoms, e.g.
$\mathrm{COCl} 2, \mathrm{POCl} 3, \mathrm{XeO} 2 F 2$ etc. Let us take the case of POCI3. $\quad H=\frac{1}{2}(5+3-0+0)=4$. Thus, the nature of hybridization in POCl 3 is sp 3 .

Type : (D) When the species is a cation, e.g. $\mathrm{NH} 4+, \mathrm{CH} 3+, \mathrm{H} 3 \mathrm{O}+$ etc. Let us take the case of
$\mathrm{CH} 3+$. $H=\frac{1}{2}(4+3-1+0)=3$ . Thus, the hybridization in $\mathrm{CH} 3+$ is sp 2 .

Type : (E) When the species is an anion, e.g. SO42-, CO32-, PO43-, NO2-, NO3-, etc. Let us take the case of SO42-. $H=\frac{1}{2}(6+0-0+2)=4$. Thus, hybridization in $\mathrm{SO}_{4}^{2-}$ is $\mathrm{sp3}$.

Type : (F) When the species is a complex ion of the type ICl4-, I3-, ClF2-, etc. Let us take the case of CIF2-. $\quad H=\frac{1}{2}(7+2-0+1)=5$. Thus, in CIF2-, Cl is sp3d hybridized.

Type : (G) When the species is a complex ion of the type [PtF6]2 -, [Co(NH3)6]2+, [ $\mathrm{Ni}(\mathrm{NH} 3) 4 \mathrm{Cl} 2]$ etc. In such cases nature of hybridization is given by counting the co-ordination number.

Important Tips

The sequence of relative energy and size of $s-p$ type hybrid orbitals is $s p<s p 2<s p 3$.
The relative value of the overlapping power of $\mathrm{sp}, \mathrm{sp} 2$ and sp 3 hybrid orbitals are 1.93, 1.99 and 2.00 respectively.

An increase in s-character of hybrid orbitals, increases the bond angle. Increasing order of s -characters and bond angle is $\mathrm{sp} 3<\mathrm{sp} 2<\mathrm{sp}$.

Normally hybrid orbitals (sp, sp2, sp3, dsp2, dsp3 etc.) form $\sigma$-bonds but in benzyne lateral overlap of sp2-orbitals forms a $\pi$-bond.

Some iso-structural pairs are ${ }^{\left[\mathrm{NF}_{3}, \mathrm{H}_{3} \mathrm{O}^{+}\right],\left[\mathrm{NO}_{3}^{-}, \mathrm{BF}_{3}\right],\left[\mathrm{SO}_{4}^{2-}, \mathrm{BF}_{4}^{-}\right]}$. There structures are similar due to same
hybridization.
In BF3 all atoms are co-planar.
In PCl 5 the state of hybridization of P atom is sp 3 d . In its trigonal bipyramidal shape all the $\mathrm{P}-\mathrm{Cl}$ bonds are not equal.

The $\pi$ bond formed between S and O atoms in SO 2 molecule is due to overlap between their p -orbitals ( $P \pi-P \pi$ bonding) or between p orbital of O -atom with d -orbital of S -atom (called $\mathrm{p} \pi-\mathrm{d} \pi$ bonding) ${ }_{16} S=1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p_{x}^{2} 3 p_{y}^{1} 3 p_{z}^{1} \quad$ (Ground state configuration) $=1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p_{x}^{1} 3 p_{y}^{1} 3 p_{z}^{1} 3 d^{1} \quad$ (Excited state configuration)
${ }_{8} O=1 s^{2} 2 s^{2} 2 p_{x}^{2} 2 p_{y}^{1} 2 p_{z}^{1}$

S -atom undergoes sp 2 hybridization leaving one half-filled 3 pz orbital and one d -orbital unhybridized. Out of two half filled orbitals of O -atom, one is involved in formation of $\sigma$-bond with S -atom and the other in forming $\pi$-bond.
